#### Abstract

The cross sections of the $e^{+} e^{-} \rightarrow K^{+} K^{-}$process are measured precisely at center-of-mass energies $\sqrt{s}$ from 2.00 to 3.08 GeV using data collected with the BESIII detector operating at the Beijing Electron Positron Collider (BEPCII). The results are consistent with the previous measurements but with better precision. A resonant structure around 2.2 GeV is observed in the cross section line shape. A fit to the line shape yields a mass of $m=2245.6 \pm 8.3 \pm 10.8 \mathrm{MeV} / c^{2}$ and a width of $\Gamma=136.3 \pm 11.8 \pm 9.2 \mathrm{MeV}$, where the first uncertainty is statistical and the second is systematic. In addition, the kaon form factors are extracted from the cross sections.

## I. INTRODUCTION

With the observation of new structures in the $\phi-\psi^{172}$ region [1-4], it is of great interest to know if they are ${ }^{173}$ excited states of $\rho, \omega, \phi$ or possible exotic particles, e.g. ${ }^{174}$ glueballs, hybrid mesons [5] or others. The identification ${ }^{175}$ of these particles requires better understanding of their ${ }^{176}$ decay patterns which can be investigated with exclusive ${ }^{177}$ processes in $e^{+} e^{-}$annihilations [6]. The knowledge of the ${ }^{178}$ $e^{+} e^{-} \rightarrow K^{+} K^{-}$process can reveal properties of $\rho, \omega, \phi^{179}$ and their excited states, e.g. $\phi(2170)$ is predicted to de- ${ }^{180}$ cay to kaon pairs according to the model in Ref. [7]. The ${ }^{181}$ form factor of the light mesons is also interesting and ${ }^{182}$ helps to understand the internal dynamics of hadrons, ${ }^{183}$ the detailed structure of hadronic wavefunctions, and the ${ }^{184}$ nuclear and hypernuclear forces $[8,9]$. Furthermore, the ${ }^{185}$ asymptotic QCD can also be tested from the measure--186 ment of the kaon form factor at high energies, where the ${ }^{187}$ form factor $F_{K}$ is predicted to be inversely proportional ${ }^{188}$ to the square of $s$.

189
Many efforts have been deployed to understand the ${ }^{190}$ $e^{+} e^{-} \rightarrow K^{+} K^{-}$process [10-16]. In the energy region ${ }^{191}$ around the $\phi(1020)$ resonance, the uncertainties of the ${ }^{192}$ previous measured cross sections are of a few percent, ${ }^{193}$ while they are more than $15 \%$ for energies higher than ${ }^{194}$ 2.0 GeV . The $B A B A R$ experiment used initial-state ra-195 diation (ISR) technique to measure the $e^{+} e^{-} \rightarrow K^{+} K^{-196}$ process in a wide energy range from the threshold of ${ }^{197}$ $K^{+} K^{-}$to 8 GeV and observed complicated structures ${ }^{198}$ between 1.8 and $2.4 \mathrm{GeV}[12,13]$. In this paper, the ${ }^{199}$ $e^{+} e^{-} \rightarrow K^{+} K^{-}$process has been studied with the en-200 ergy scan method at 22 energies from 2.00 to 3.08 GeV .201 The uncertainties of the cross section measurement and ${ }^{202}$ the kaon form factor are reduced significantly.

## II. DETECTOR AND DATA SAMPLES

BEPCII [17, 18] is a double-ring $e^{+} e^{-}$collider de- ${ }^{208}$ signed to provide a peak luminosity of $10^{33} \mathrm{~cm}^{-2} \mathrm{~s}^{-1}$ at $\sqrt{s}=3.770 \mathrm{GeV}$. The BESIII $[17,19]$ detector has a geometrical acceptance of $93 \%$ of the full solid angle ${ }^{209}$ and has four main components: (1) A small-cell, heliumbased $\left(60 \% \mathrm{He}, 40 \% \mathrm{C}_{3} \mathrm{H}_{8}\right)$ main drift chamber (MDC) $)_{210}$ with 43 layers providing an average single-hit resolution 211 of $135 \mu \mathrm{~m}$, and a momentum resolution in a 1 T mag-212 netic field of $0.5 \%$ at $1 \mathrm{GeV} / c$; (2) An electromagnetic 213 calorimeter (EMC) in a cylindrical structure consisting ${ }_{214}$
of one barrel and two endcaps. The energy resolution for tracks with $1.0 \mathrm{GeV} / \mathrm{c}$ momentum is $2.5 \%(5 \%)$ in the barrel (endcaps), and the position resolution is 6 mm ( 9 mm ), respectively; (3) A time of flight system is used for particle identification. It is composed of 5 -cm-thick plastic scintillators, with 176 detectors of 2.4 m length in two layers in the barrel and 96 fan-shaped detectors in the endcaps. The barrel (endcaps) time resolution of 80 $\mathrm{ps}(110 \mathrm{ps})$ provides $2 \sigma K / \pi$ separation for momenta up to $1.0 \mathrm{GeV} / c$; (4) The muon system (MUC) consists of $1272 \mathrm{~m}^{2}$ of resistive plate chambers (RPCs) in nine barrel and eight endcap layers and provides 2 cm position resolution.

The data samples used in this analysis correspond to a total integrated luminosity of $651 \mathrm{pb}^{-1}$, collected at 22 center-of-mass (c.m.) energies between 2.00 and 3.08 GeV .

Monte Carlo (MC)-simulated signal and background samples are used to optimize the event selection criteria, estimate the background contamination and evaluate the selection efficiencies. The MC samples are generated using a Geantu-based [20] simulation software package Besiif Object Oriented Simulation Tool [21], which includes the description of geometry and material, the detector response and the digitization model, as well as a database of the detector running conditions and performance.

In this analysis, the generator software package CONEXC [22] is used to simulate the signal MC samples $e^{+} e^{-} \rightarrow K^{+} K^{-}$, and calculate the corresponding correction for higher-order processes with one radiative photon in the final states. Simulated samples of the QED background processes $e^{+} e^{-} \rightarrow e^{+} e^{-}, \mu^{+} \mu^{-}$and $\gamma \gamma$ are generated with the generator babayaga [23]. The other background of the $e^{+} e^{-} \rightarrow$ hadrons and the $e^{+} e^{-} \rightarrow e^{+} e^{-} X$ ( $X$ can be hadrons or leptons) processes are generated with the generators Luarlw [24] and Bestwogam [25], respectively.

## III. EVENT SELECTION

The signal events are required to have two good oppositely charged tracks, which are reconstructed with the hit information from the MDC. A good charged track must be within the MDC coverage, $|\cos \theta|<0.93$, and is required to pass within 1 cm of the $e^{+} e^{-}$interaction
point in the plane perpendicular to the beam and within $\pm 10 \mathrm{~cm}$ in the direction along the beam. To suppress the $e^{+} e^{-} \rightarrow(\gamma) e^{+} e^{-}$background, two selection criteria are required. Firstly, the ratio $E / p$ of each kaon candidate is required to be smaller than a certain value to maximize the signal to background ratio, where $E$ and $p$ are the energy deposited in the EMC and the momentum measured in the MDC, respectively. Secondly, the event should satisfy $\cos \theta_{+}<0.8$ for the positive track and $\cos \theta_{-}>-0.8$ for the negative track. To suppress multi-body processes, the opening angle between the two tracks in the $e^{+} e^{-}$ c.m. system is required to be larger than $179^{\circ}$. The background from cosmic rays is rejected by requiring the difference of TOF recorded time between the two tracks to be less than 3 ns . Figure 1 and 2 show comparisons of the angular distributions between experimental data and MC simulation at $\sqrt{s}=2.6444 \mathrm{GeV}$. There is good agreement between data and MC simulations.

The momenta of the $K^{ \pm}$tracks are expected to be $p_{\exp }=\sqrt{s / 4-m_{K}^{2}}$, which allows to effectively distin-

FIG. 1. Polar angular distribution of positive (upper) and negative (lower) tracks at 2.6444 GeV after performing all se- ${ }^{240}$ lection criteria, as well as a requirement that the momenta of ${ }^{241}$ both tracks should be within $3 \sigma_{p}$ region of the signal, where ${ }^{242}$ is $\sigma_{p}$ is the momentum resolution. The arrows show the se-243 lection requirements on the polar angular distribution of the ${ }_{244}$ tracks to suppress $e^{+} e^{-} \rightarrow(\gamma) e^{+} e^{-}$background. "MC sum" ${ }_{245}$ in the legend means the sum of signal, $e^{+} e^{-} \rightarrow(\gamma) \mu^{+} \mu^{-}$and $_{246}$ $e^{+} e^{-} \rightarrow(\gamma) e^{+} e^{-}$MC.

FIG. 2. Opening angle between the positive and the negative tracks at $\sqrt{s}=2.6444 \mathrm{GeV}$ after performing all selection criteria, as well as a requirement that the momenta of the negative track should be within $3 \sigma_{p}$ region of the signal. The arrow shows the selection requirement on the opening angle.
guish the signal from other two-body processes. Figure 3 shows the scatter plot of momentum distribution of the two tracks after performing all selection criteria described above.

FIG. 3. Scatter plot of the momentum distribution of the positive $\left(p_{+}\right)$and the negative $\left(p_{-}\right)$track at $\sqrt{s}=2.6444 \mathrm{GeV}$. The signal events ( $3 \sigma_{p}$ region as shown in box) are concentrated around $p_{\exp }=1.23 \mathrm{GeV} / c$.

## IV. BACKGROUND ANALYSIS

The potential background may come from hadronic processes with multi-body final states, or the $e^{+} e^{-}$annihilation processes with two-body final states, e.g. $e^{+} e^{-}$, $\mu^{+} \mu^{-}$and $\pi^{+} \pi^{-}$, where a radiative process can reduce the momenta of final particles to the momentum region of kaon. The contamination of the background is evaluated by MC simulations in $3 \sigma_{p}$ momentum region of the signal, where $\sigma_{p}$ is the momentum resolution determined with
signal MC. After imposing the above selection criteria, 274 no events survived in $e^{+} e^{-} \rightarrow(\gamma) e^{+} e^{-}, \gamma \gamma$, and $e^{+} e^{-} X_{275}$ processes. The background in hadronic final states is few ${ }_{276}$ and can be neglected. The dominant background comes ${ }_{277}$ from $e^{+} e^{-} \rightarrow(\gamma) \mu^{+} \mu^{-}$and the normalized number of ${ }_{278}$ events in this process is summarized in Table I. The ${ }_{279}$ background level, defined as the ratio of the number of $\mathrm{f}_{20}$ the background events to that of the signal, varies from ${ }_{281}$ $0.5 \%$ to $60 \%$ in dependence of c.m. energies and no peaks are observed in the signal region from background processes.

## V. CROSS SECTION AND FORM FACTOR

## A. Signal extraction

The number of signals is extracted by fitting the $\mathrm{mo}^{287}$ mentum spectrum of the positive track while the mo- ${ }^{288}$ mentum of the negative track is required to be within ${ }^{289}$ $\left(p_{\exp }-3 \sigma_{p}, p_{\exp }+3 \sigma_{p}\right)$. In the fit, the signal is described ${ }^{290}$ by the signal MC shape convoluted with a Gaussian func- ${ }^{291}$ tion and background is described with the MC shape of ${ }^{292}$ the $e^{+} e^{-} \rightarrow(\gamma) \mu^{+} \mu^{-}$process convoluted with another ${ }^{293}$ Gaussian function. The convoluted Gaussian functions ${ }^{294}$ are supposed to composite the possible resolution devi- ${ }^{295}$ ation between data and MC simulation. Figure 4 illus- ${ }^{296}$ trates the fit result at $\sqrt{s}=2.6444 \mathrm{GeV}$.

FIG. 4. Momentum spectrum at $\sqrt{s}=2.6444 \mathrm{GeV}$. Solid line ${ }^{312}$ represents the total fit function. Dash lines are signal (main313 part of left peak) and background (right peak and its tail). 314

## B. Efficiency and correction factor

The Born cross section is calculated from

$$
\begin{equation*}
\sigma^{B}=\frac{N_{\mathrm{sig}}}{\mathcal{L} \cdot \epsilon \cdot(1+\delta)}, \tag{1}
\end{equation*}
$$

where $N_{\text {sig }}$ is the number of signal events, $\mathcal{L}$ is the integrated luminosity measured with method mentioned in [26], $\epsilon$ is the detection efficiency, $1+\delta$ is the correction factor due to ISR and vacuum polarization (VP).

The detection efficiency and the correction factor are obtained from the signal MC generated at each energy. In the generator, the cross section for ISR process $\left(\sigma_{e^{+} e^{-} \rightarrow \gamma X_{i}}\right)$ is determined with the relation [22]

$$
\begin{equation*}
\sigma_{e^{+} e^{-} \rightarrow \gamma X_{i}}=\int d \sqrt{s^{\prime}} \frac{2 \sqrt{s^{\prime}}}{s} W(s, x) \frac{\sigma^{B}\left(s^{\prime}\right)}{\left[1-\Pi\left(s^{\prime}\right)\right]^{2}} \tag{2}
\end{equation*}
$$

where $\sqrt{s^{\prime}}$ is the effective c.m. energy of final states with $s^{\prime}=s(1-x)$, and $x \equiv 2 E_{\gamma} / \sqrt{s}$ with $E_{\gamma}$ representing the energy of the radiated photon, $\Pi\left(s^{\prime}\right)$ represents the VP effect, which includes contributions from leptons and quarks, and $W(s, x)$ is the radiator function. To obtain a reliable detection efficiency $\epsilon$ and correction factor $1+\delta$, an iterative procedure is performed. Firstly, the $B A B A R$ 's cross sections are used as an initial line shape to generate signal MC. Then the calculated Born cross sections in this analysis with $B A B A R$ 's result are fitted with a phenomenological function, which is used as the input line shape. The procedure is repeated until the difference between last two iterations is less than $0.5 \%$, thereby the iterative procedure is regarded as converged.To obtain a reliable detection efficiency $\epsilon$ and correction factor $1+\delta$, an iterative procedure is performed.

For energies near the $J / \psi$ resonance, the $J / \psi \rightarrow K^{+} K^{-}$and the $e^{+} e^{-} \rightarrow K^{+} K^{-}$processes interfere with each other. To correct the contribution from $J / \psi$ decay and the interference, we use another data sample collected for $J / \psi$ resonance study to extract the correction factor. In the extraction, we use a function containing amplitudes of the $J / \psi$ decay and the continuum contribution to fit the line shape of the $K^{+} K^{-}$cross section and take the ratio of continuum contribution and total cross section as the correction factor. The Born cross sections and related variables are summarized in Table I.

## C. Line shape of $e^{+} e^{-} \rightarrow K^{+} K^{-}$

The measured Born cross sections shown in Fig. 5 are consistent with that of the $B A B A R$ experiment but with better precision. The line shape of cross sections is fitted with [12, 27]

$$
\begin{equation*}
\sigma^{B}=\left|A_{K}\right|^{2} \tag{3}
\end{equation*}
$$

where the amplitude is written as

$$
\begin{align*}
A_{K} & =c_{\phi} B W_{\phi}+c_{\phi^{\prime}} B W_{\phi^{\prime}}+c_{R 1} B W_{R 1} \\
& +c_{\rho} B W_{\rho}+c_{\rho^{\prime}} B W_{\rho^{\prime}}+c_{\rho^{\prime \prime}} B W_{\rho^{\prime \prime}}+c_{R 2} B W_{R 2} \\
& +c_{\omega} B W_{\omega}+c_{\omega^{\prime}} B W_{\omega^{\prime}}+c_{\omega^{\prime \prime}} B W_{\omega^{\prime \prime}}+c_{R 3} B W_{R 3}  \tag{4}\\
& +c_{c o n} \cdot s^{-\alpha} \cdot e^{i \cdot \theta},
\end{align*}
$$

where $c$ 's are coefficients of resonances, including ${ }_{336}$ $\phi=\phi(1020), \phi^{\prime}=\phi(1680), \rho=\rho(770), \rho^{\prime}=\rho(1450)$, ,337 $\rho^{\prime \prime}=\rho(1700), \omega=\omega(782), \omega^{\prime}=\omega(1420), \omega^{\prime \prime}=\omega(1650)_{338}$ and other resonances whose parameters are to be deter-339 mined due to the lack of corresponding states in PDG,340 $R 1$ denotes the structure around 2.23 GeV , while $R 2$ and $_{341}$ $R 3$ are introduced to compensate some unknown contri-342 bution to the line shape. $s^{-\alpha}$ is used to describe the ${ }_{343}$ continuum process, $\theta$ is the relative phase between res-344 onances and continuum process, $B W$ s are Breit-Wigner ${ }_{345}$ functions of resonances, which take the form

$$
\begin{equation*}
B W(s, m, \Gamma(s))=\frac{1}{m^{2}-s-i \sqrt{s} \Gamma(s)} \tag{5}
\end{equation*}
$$

349
where $m$ is the mass of resonances. The width $\Gamma(s)$ of $^{350}$ a resonance is energy dependent. For the $\rho$ resonance, ${ }_{352}^{351}$ energy dependence is given by

$$
\begin{equation*}
\Gamma_{\rho}(s)=\Gamma_{\rho} \frac{s}{m_{\rho}^{2}}\left(\frac{\beta\left(s, m_{\pi}\right)}{\beta\left(m_{\rho}^{2}, m_{\pi}\right)}\right)^{3} \tag{6}
\end{equation*}
$$

with $\beta(s, m)=\sqrt{1-4 m^{2} / s}$. For the $\phi$ resonance, there ${ }_{356}$ are separate contributions from different decay modes, thereby the total width is parameterized in an approxi- ${ }_{357}$ mate way as

$$
\begin{align*}
\Gamma_{\phi}(s)= & \Gamma_{\phi}\left[\mathcal{B}\left(\phi \rightarrow K^{+} K^{-}\right) \frac{\Gamma_{\phi \rightarrow K^{+} K^{-}}(s)}{\Gamma_{\phi \rightarrow K^{+} K^{-}}\left(m_{\phi}^{2}\right)}\right. \\
& +\mathcal{B}\left(\phi \rightarrow K^{0} \bar{K}^{0}\right) \frac{\Gamma_{\phi \rightarrow K^{0} \bar{K}^{0}}(s)}{\Gamma_{\phi \rightarrow K^{0} \bar{K}^{0}}\left(m_{\phi}^{2}\right)}  \tag{7}\\
& \left.+1-\mathcal{B}\left(\phi \rightarrow K^{+} K^{-}\right)-\mathcal{B}\left(\phi \rightarrow K^{0} \bar{K}^{0}\right)\right]
\end{align*}
$$

where $\Gamma_{\phi \rightarrow K \bar{K}}(s)$ is similar to Eq. (6) but with $\rho$ replaced by $\phi$ and $\pi$ replaced by $K$, respectively, $\mathcal{B}$ is the Branch-

FIG. 5. Born cross section of the $e^{+} e^{-} \rightarrow K^{+} K^{-}$process. ${ }^{376}$ Soft dots (in blue) and triangles with error bar are results of $B A B A R$. Solid dots (in red) are results of BESIII (this ${ }_{377}$ work). The error bars include both statistical and systematic ${ }_{378}$ uncertainties. The fit is performed on both data from BESIII ${ }_{379}$ and $B A B A R$ using Eq. (3).
ing fraction. Fixed widths are used for resonances other than $\phi$ and $\rho$.

Masses and widths of $\left(\phi, \phi^{\prime}\right),\left(\rho, \rho^{\prime}, \rho^{\prime \prime}\right)$ and $(\omega$, $\left.\omega^{\prime}, \omega^{\prime \prime}\right)$ are set to the values from Particle Data Group (PDG) [1], while masses and widths of $\phi^{\prime \prime}, \rho^{\prime \prime \prime}$ and $\omega^{\prime \prime \prime}$ are free. Parameters of resonances are determined from the $B A B A R$ 's cross sections below 2.00 GeV and from both the $B A B A R$ 's and the BESIII's measurement between 2.00 and 3.08 GeV . In the fit, statistical and systematic uncertainties are taken into consideration. For the BESIII's cross sections, systematic uncertainties from the ISR and the VP, the luminosity and the tracking efficiency are supposed as correlated while other uncertainties are treated as uncorrelated. The uncertainties of $B A B A R$ 's cross section are simply treated as uncorrelated. A structure with $m=2245.6 \pm 8.3 \mathrm{MeV} / c^{2}$ and $\Gamma=136.3 \pm 11.8 \mathrm{MeV}$ is observed, as shown in Fig. 5. The amplitude of the resonance is not easy to extract because it is hard to determine the interference among several uncertain resonances used here.

## D. Form factor

Experimentally, the form factor of charged kaon can be calculated from the cross section using following formula [12]

$$
\begin{equation*}
\left|F_{K}\right|^{2}(s)=\frac{3 s}{\pi \alpha(0)^{2} \beta_{K}^{3}} \frac{\sigma^{D}}{C_{\mathrm{FS}}}, \tag{8}
\end{equation*}
$$

where

$$
\begin{equation*}
\sigma^{D}=\sigma^{B}\left(\frac{\alpha(s)}{\alpha(0)}\right)^{2} \tag{9}
\end{equation*}
$$

is the dressed cross section, derived from the Born cross section $\sigma^{B}, \alpha(s)$ is the electromagnetic coupling constant, $\beta_{K}=\sqrt{1-4 m_{K}^{2} / s}$ is the kaon velocity, and $C_{\mathrm{FS}}$ is the final-state correction [29-31]. The form factors can be found in Table I.

The asymptotic QCD predicts that the form factor of a spin zero meson is $F_{K}=16 \pi \alpha_{s}(s) f_{K}^{2} / s[28]$, where $\alpha_{s}(s)$ is the strong coupling constant and $f_{K}$ is the weak decay amplitude of charged kaon. A fit to $\left|F_{K}\right|^{2}$ is performed with a function $A \alpha_{s}^{2}(s) / s^{n}$ at $\sqrt{s}>2.38 \mathrm{GeV}$. $A$ and $n$ are allowed to vary in the fit as shown in Fig. 6. It is obtained that $n=1.94 \pm 0.09$ which is in agreement with the QCD prediction $n=2$. The fit is not implemented at lower energy range because there are resonances which can not be described by the function.

## VI. SYSTEMATIC UNCERTAINTY

Several sources of systematic uncertainties are considered in the measurement of the Born cross section and the corresponding form factors, including those of the detection efficiency, the luminosity, the ISR and VP correction

TABLE I. Cross sections of $e^{+} e^{-} \rightarrow K^{+} K^{-}$process and form factors of kaon. $N_{\text {sig }}$ is the number of signal events, excluding the number of survived $\mu^{+} \mu^{-}$events $N_{\mu \mu}^{\mathrm{MC}}$ in the signal region estimated from MC simulation, along with detection efficiency $\epsilon$, radiative correction factor $1+\delta$, and luminosity $\mathcal{L} . \sigma^{B}$ is the measured Born cross section, form which the form factor $F_{K}$ is extracted. The first uncertainties are statistical and the second ones systematic. Uncertainties of form factor are propergated from those of cross sections.

FIG. 6. $\left|F_{K}\right|^{2}$ of $e^{+} e^{-} \rightarrow K^{+} K^{-}$. Dots (in black) are results ${ }^{403}$ in this work. Solid Line (in blue) is the fit result at $\sqrt{s}>2.38^{404}$ GeV while dotted line is extrapolation of solid line to show ${ }^{405}$ the trend of pQCD prediction at lower energy.
factor, background shape, and signal shape. The uncer-409 tainty sources for the detection efficiency include system- ${ }^{410}$ atic uncertainties in tracking efficiency, the $p$ and $E / p$ re-411 quirements, opening angle between the positive and the ${ }^{412}$ negative tracks, and the MC statistics. The uncertainty ${ }^{413}$ of tracking efficiency is investigated using a control sam- ${ }^{414}$ ple $e^{+} e^{-} \rightarrow K^{+} K^{-} \pi^{+} \pi^{-}$with the strategy described ${ }^{415}$ in Ref [32]. Kaons have momenta that range from $0.85^{416}$

## 

to $1.45 \mathrm{GeV} / c$, and their transverse-momentum-weighted tracking efficiency is about $1 \%$ per track. For the $p, E / p$ and opening angle requirements, the distributions of corresponding variables in MC simulation are smeared to those in data and the differences of cross sections under the same requirements are taken as the systematic uncertainties. The uncertainty of MC statistics is estimated by $\Delta_{M C}=\frac{1}{\sqrt{N}} \cdot \sqrt{\frac{1-\epsilon}{\epsilon}}$, where $N$ is the number of signal MC events. The integrated luminosities are measured using large angle Bhabha scattering events, with an uncertainty of about $1 \%$ [26]. In the ISR and VP correction procedure, the cross section measurement is iterated until $(1+\delta) \epsilon$ converges. The difference between last two iterations is taken as the systematic uncertainty. Uncertainties due to the choice of the signal shape and background shapes, and the fit range are estimated by changing signal and background functions, and the fit range, respectively. All systematic uncertainties of cross section measurement are summarized in Table II.

The systematic uncertainties in the resonance parameters come from the absolute c.m. energy measurement, the systematic uncertainty on the cross section measurement, and the model used to describe the resonance. The uncertainty of c.m. energy provided by BEPCII is small and negligible in the extraction of the resonance parameters. The systematic uncertainty of the cross section measurement has already been considered in the fit of the cross section line shape. To assess the system-
atic uncertainty connected with the model, a modified 451 Breit-Wigner function, considering the vertex function ${ }_{452}$ and phase space factor, is used to describe the resonance. 453 The systematic uncertainties of the mass and the width are $6.2 \mathrm{MeV} / c^{2}$ and 0.9 MeV , respectively. The width the resonance is quite large, which may be energy-dependent.454 If we parameterized the width to be similar with $\Gamma_{\rho}$, this will introduce an uncertainty of $3.6 \mathrm{MeV} / c^{2}$ and $5.4 \mathrm{MeV}_{455}$ for mass and width, respectively. Besides the Breit-456 Wigner function, the model is based on a sum of several ${ }_{457}$ resonances and parameters for some of them are quoted $d_{458}$ from PDG. The uncertainties due to the quoted parame-459 ters are estimated by sampling the parameters for many $4_{460}$ times according to their masses and uncertainties in $\mathrm{PDG}_{461}$ with Gaussian assumption. The systematic uncertainties ${ }_{462}$ are estimated to be $8.8 \mathrm{MeV} / c^{2}$ and 9.2 MeV for mass $_{463}$ and width, respectively. The overall systematic uncer-464 tainties are obtained by summing all independent uncer-465 tainties in quadrature, which are $11.4 \mathrm{MeV} / c^{2}$ for $\operatorname{mass}_{466}$ and 10.7 MeV for width

## VII. CONCLUSION

In summary, we measure the $e^{+} e^{-} \rightarrow K^{+} K^{-}$Born $_{472}$ cross section and charged kaon form factor using data473 samples at 22 c.m. energies from 2.00 to 3.08 GeV with ${ }_{474}$ much better precision compared to previous results. A475 fit of the charged kaon form factor has been performed ${ }_{476}$ at c.m. energy above 2.38 GeV and confirms the $\mathrm{QCD}_{477}$ prediction that $\left|F_{K}\right|$ decreases with $1 / s$. The line shape478 of the cross section is fitted using a model based on a479 sum of resonances and yield a structure with a mass of 480 $2245.6 \pm 8.3 \pm 10.8 \mathrm{MeV} / c^{2}$ and a width of $136.3 \pm 11.8 \pm_{481}$ 9.2 MeV , where the first uncertainties are statistical and $4_{82}$ the second ones are systematic. The nominal mass of the $4_{83}$ resonance is consistent with the $\rho(2150)$ and the $\phi(2170)_{484}$
within $2 \sigma$. However, the width deviations are more than $2 \sigma$, wider than that of the $\phi(2170)$ but narrower than that of $\rho(2150)$, and therefore further study is needed.

## VIII. ACKNOWLEDGEMENT

The BESIII collaboration thanks the staff of BEPCII, the IHEP computing center and the supercomputing center of USTC for their strong support. This work is supported in part by National Key Basic Research Program of China under Contract No. 2015CB856700; National Natural Science Foundation of China (NSFC) under Contracts Nos. 11235011, 11335008, 11425524, 11625523, 11635010; the Chinese Academy of Sciences (CAS) Large-Scale Scientific Facility Program; the CAS Center for Excellence in Particle Physics (CCEPP); Joint LargeScale Scientific Facility Funds of the NSFC and CAS under Contracts Nos. U1332201, U1532257, U1532258; CAS under Contracts Nos. KJCX2-YW-N29, KJCX2-YW-N45, QYZDJ-SSW-SLH003; 100 Talents Program of CAS; National 1000 Talents Program of China; INPAC and Shanghai Key Laboratory for Particle Physics and Cosmology; German Research Foundation DFG under Contracts Nos. Collaborative Research Center CRC 1044, FOR 2359; Istituto Nazionale di Fisica Nucleare, Italy; Koninklijke Nederlandse Akademie van Wetenschappen (KNAW) under Contract No. 530-4CDP03; Ministry of Development of Turkey under Contract No. DPT2006K-120470; National Science and Technology fund; The Swedish Resarch Council; U. S. Department of Energy under Contracts Nos. DE-FG02-05ER41374, DE-SC-0010118, DE-SC-0010504, DE-SC-0012069; University of Groningen (RuG) and the Helmholtzzentrum fuer Schwerionenforschung GmbH (GSI), Darmstadt; WCU Program of National Research Foundation of Korea under Contract No. R32-2008-000-10155-0
